

# Package ‘eRNAkit’

April 22, 2025

**Type** Package

**Title** A tool kit for characterising eRNA regulatory functions beyond the nucleus.

**Version** 0.2.1

**Description** eRNAkit, is a comprehensive and accessible resource designed to address the gap in non-canonical eRNA functions in humans.

It includes an array of analytical workflows, db integrating eRNA subcellular localisation, RNA–RNA interaction and expression.

It also includes a ui app "eRNAkitApp" to interactively explore the db.

**License** GPL-3

**Encoding** UTF-8

**LazyData** true

**RoxygenNote** 7.3.2

**Imports** mgcv,  
Biostrings,  
GenomicRanges,  
tidyr

byRange	<i>Find Overlaps Between emi\$score and a Genomic Coordinate String</i>
---------	---

---

## Description

Parses a coordinate string and finds overlapping entries in a emi\$score. Returns a data.frame including all metadata columns.

## Usage

```
byRange(erob, s)
```

## Arguments

erob	A ‘GRanges’ object to search within.
s	A character string in the format "chr1:100-200" or "1:100-200".

## Value

A data.frame of overlapping GRanges entries with metadata columns. Returns an empty data.frame if no overlaps are found.

## Examples

```
find_overlap_df(my_gr, "chr1:2000-3000")
```

---

check_null	<i>Check if all elements of a db "emi" is NULL.</i>
------------	---

---

**Description**

This is specific for Dr. Anene's DBs. It is likely useful after subsetting the DB.

**Usage**

```
check_null(db)
```

**Arguments**

db	The DB object to check for NULL
----	---------------------------------

**Value**

TRUE if all elements are NULL or FALSE.

---

chimericPRO	<i>Process chimeric junction file from star-alignment.</i>
-------------	--

---

**Description**

Function to process chimeric junction files into a bedpe format. It splits the pairs to make it easy to find overlaps.

**Usage**

```
chimericPRO(file)
```

**Arguments**

file	The file path for the chimeric.junction from star.
------	--

**Value**

A list with n1 and n2 pairs. The name column match the ID.

---

compute_mad	<i>Compute median absolute deviation with constant.</i>
-------------	---

---

**Description**

Compute median absolute deviation with constant.

**Usage**

```
compute_mad(x)
```

**Arguments**

x	A vector of values to compute.
constant	The constant value to add mad equal to 0.
na.rm	Option to remove "TRUE" or not "FALSE" NA values.

**Value**

MAD for each value in the vector

**Examples**

```
compute_mad(c(2, 4, 7, 8,9))
```

---

eeCigar	<i>Extract end coordinates from cigar string.</i>
---------	---

---

**Description**

Function to extract end position from cigar string. The function only adds M, D and S to the count.

**Usage**

```
eeCigar(start = 2, strand = "+", cigar = "10M5D20M2I")
```

**Arguments**

start	Start position.
strand	The strand. Default is + standard.
cigar	The cigar string.

**Value**

The end coordinate.

entropyTS

*Compute Tissue/Cell Type Specificity Scores***Description**

This function calculates specificity scores for eRNA or genes based on their expression profiles across multiple tissues or cell types. The specificity score is computed using Shannon entropy and a logarithmic correction.

**Usage**

entropyTS(x)

**Arguments**

**x** A data frame or matrix where rows represent eRNAs and columns represent different tissues or cell types. Only numeric columns (expression values) are used for calculations.

**Details**

The function follows these steps:

1. Compute expression ratios by normalizing each eRNA's expression across tissues/cell types.
2. Calculate Shannon entropy for each eRNA.
3. Compute the specificity score as  $\log_2(N) - H$ , where  $\log_2(N)$  is the number of cell types and  $H$  is Shannon entropy.
4. Define specificity by checking if the highest expression ratio is at least 2× the second highest and if the specificity score is greater than 1.

**Value**

A data frame with three columns:

**ID** The identifier (row names of input data).

**Specificity\_Score** The calculated specificity score for each row.

**Is\_Specific** The tissue/cell type where the transcript is specific, or FALSE if not specific.

eRNASeq

*Extract eRNA sequences from a FASTA file using BED coordinates***Description**

This function extracts DNA sequences for eRNAs from a reference FASTA file based on coordinates provided in a BED file. It optionally supports strand-specific extraction and writes the result to a new FASTA file.

**Usage**

eRNASeq(b, fasta)

**Arguments**

- b** Data frame with intervals. It must "chr", "start", "end", "strand" as names. With any other mcols.
- fasta** Character. Path to the reference genome in FASTA format.

**Value**

A DNASTringSet object containing the extracted sequences.

---

eRnkitApp	<i>Lunch eRNAkit Web application.</i>
-----------	---------------------------------------

---

**Description**

This lunches the eRNAkit UI for interactive exploration of the emi db.

**Usage**

```
eRnkitApp()
```

**Value**

The Web UI

---

getGRange	<i>Get genomic range object for annGE or chimericPRO.</i>
-----------	---

---

**Description**

Make GRanges object from dataframe. This function expects a specific input so make sure you have that. It must have columns named "chr", "start", "end", "strand"

**Usage**

```
getGRange(tab = exmp)
```

**Arguments**

**tab**

**Value**

Returns GRanges

---

listDB	<i>List all database from the eRNAkit.</i>
--------	--

---

**Description**

Function to list DB .rds included with the eRNAkit.

**Usage**

```
listDB()
```

**Value**

A character list of all the dbs included

**Examples**

```
listDB()
```

---

loadDB	<i>Load a database from the eRNAkit.</i>
--------	--

---

**Description**

Function to load DB .rds DB into environment.

**Usage**

```
loadDB(name)
```

**Arguments**

name	Name of the db set to load (without .rds)
------	---

**Value**

The loaded R object

**Examples**

```
ribo <- loadDB("ribo")
```

---

log2_count2cpm	<i>Count to log2 count per million "CPM"</i>
----------------	--

---

**Description**

Convert count to log2 CPM on matrix

**Usage**

```
log2_count2cpm(df = "data", side = "r:1.c:2")
```

**Arguments**

df: Data frame  
side: Operate on row-1 or column-2

**Value**

Data frame of converted counts

**Examples**

```
log2_count2cpm(df, 2)
```

---

make_windows	<i>Create n.bp Genomic Windows or Retain Original Interval</i>
--------------	--

---

**Description**

Given a genomic interval, this function splits it into non-overlapping windows of n base pairs if the interval length is greater than n. If the interval is shorter than or equal to n, it is returned as-is.

**Usage**

```
make_windows(chrom, start, end, name, size = 100)
```

**Arguments**

chrom A character or numeric value representing the chromosome name or number.  
start An integer representing the start coordinate of the genomic interval (1-based).  
end An integer representing the end coordinate of the genomic interval (inclusive).  
name A character string providing an identifier for the interval.  
size An integer indicating the size of the windows "n".

**Value**

A data.frame with columns chrom, start, end, and name. If the interval is longer than size, the result contains multiple rows representing the windows. For shorter intervals, a single row is returned.

---

max_cols	<i>Get id of max column by rows.</i>
----------	--------------------------------------

---

**Description**

Function to get ids of max columns in a vector. Second max column is include for future tooling. 0 values are set to NA to avoid return 0 as max.

**Usage**

```
max_cols(x)
```

**Arguments**

x                      Named vector to get max values.

**Value**

Returns the max and second max ids.

**Examples**

```
max_cols(c(A = 10, B = 20, C = 30))
```

---

max_cols_matrix	<i>Get id of max column by rows.</i>
-----------------	--------------------------------------

---

**Description**

Function to get ids of max columns in a data frame by row. Second max column is include for future tooling. 0 values are set to NA to avoid return 0 as max.

**Usage**

```
max_cols_matrix(df)
```

**Arguments**

df                      Data frame or matrix to get max values by row.

**Value**

Returns a data frame of max and second max column ids.

**Examples**

```
max_cols(matrix(1:9, nrow = 3, ncol = 3))
```

---

outlier_matrix	<i>Detect outliers in a matrix.</i>
----------------	-------------------------------------

---

### Description

Function to apply the two outlier function to a matrix. This is specific to eRNAkit usage

### Usage

```
outlier_matrix(m, type = "pnorm", name = "eRNA")
```

### Arguments

m	matrix of expression values gene/eRNA in column and sample in rows. It expects the row.names to set to gene IDs.
type	String indicating the p-value estimation method. "pnorm" or "permutation"
name	The name to use for the new gene column. This option is to differentiate eRNA/mRNA runs.

### Value

Table of results based on the output of the outlier functions.

### Examples

```
outlier_matrix(matrix(1:9, nrow = 3, ncol = 3), "pnorm")
```

---

parseGR	<i>Parse a Genomic Coordinate String into a GRanges Object</i>
---------	--

---

### Description

Takes a genomic coordinate string in the format "chr1:100-200" or "1:100-200" (case-insensitive) and returns a 'GRanges' object representing that region.

### Usage

```
parseGR(c)
```

### Arguments

c	A character string specifying the genomic region. Valid formats include "chr1:100-200", "CHR1:100-200", or "1:100-200". Whitespace is ignored. Chromosome prefix is normalized to lowercase "chr" format.
---	---

### Value

A 'GRanges' object corresponding to the parsed genomic range.

**Examples**

```

parse_genomic_range("chr1:100-200")
parse_genomic_range("CHR2:1000-2000")
parse_genomic_range("3:500-1000")

```

---

permutation\_outliers     *Detect outliers in a named vector using permutations.*

---

**Description**

Function to detect outliers in a named vector of values. It uses permutations to get empirical p-values.

**Usage**

```
permutation_outliers(x, n = 1000)
```

**Arguments**

x	A named vector of values.
n	Number of permutations to run.

**Value**

A table of all the results including intermediate tables.

**Examples**

```
permutation_outliers(c(2, 4, 7, 8,9), n=100)
```

---

plotLoc     *Plot the figures for localisation data.*

---

**Description**

This function expects tables pre-processed by the winloc function.

**Usage**

```
plotLoc(df, t = c("p1", "p2", "p3"))
```

**Arguments**

df	Data frame to plot from the winloc list of tables.
t	The type of plot p1, p2, or p3, matching the winloc table

**Value**

GGplot2 plot

plotOC

*Plot Expression Across Tissue or Cells***Description**

This function generates a bar plot showing the expression levels of eRNAs across different organs or cells. It expects the data from emi db. The data is transformed into a long format using 'pivot\_longer', excluding certain columns ('E', 'Specificity\_Score', 'Is\_Specific', 'expressed'). The plot is ordered by expression values in descending order, and a color scale is used based on the 'E' column.

**Usage**

```
plotOC(x, t = "Organ")
```

**Arguments**

**x** A data frame containing the expression data with columns representing organs or cells and an 'E' column indicating the eRNA expression values.

**t** A string specifying the column name to be used for the x-axis. Defaults to "Organ". It can be any column name in 'x' (e.g., "Cells").

**Value**

A 'ggplot' object showing the expression data as a bar plot.

**Examples**

```
# Example 2: Plot expression across cells
plotOC(x2, "Cells")
```

pnorm\_outliers

*Detect outliers in a named vector using normalized z-score.***Description**

Function to detect outliers in a named vector of values. It uses CDF of pnorm to get p-values

**Usage**

```
pnorm_outliers(x)
```

**Arguments**

**x** A named vector of values.

**Value**

A table of all the results including intermediate tables.

**Examples**

```
pnorm_outliers(c(2, 4, 7, 8,9))
```

---

remove_zeros	<i>Filter matrix to remove rows with sum 0.</i>
--------------	---

---

**Description**

Filter matrix to remove rows with sum 0.

**Usage**

```
remove_zeros(matrix)
```

**Arguments**

matrix

**Value**

The filtered matrix

**Examples**

```
remove_zeros(matrix(1:9, nrow = 3, ncol = 3))
```

---

rna2rna	<i>Extract and count the eRNA:mRNA interactions.</i>
---------	--

---

**Description**

Function to extract and count eRNA:mRNA interactions from GRanges object.

**Usage**

```
rna2rna(chimGR, geneGR, enhGR)
```

**Arguments**

chimGR	Chimeric junction GRanges object. It should be made from ChimPRO output.
geneGR	Gene annotation GRanges object. It should be made from annGE\$gene.
enhGR	Enhancer annotation GRanges object. It should be made from annGE\$erna.

**Value**

Interactions counts. Uses IDs for naming enhancer and genes.

---

rna2rnaR	<i>Extract extract locations of eRNA:mRNA interactions.</i>
----------	---

---

### Description

Function to extract locations of eRNA:mRNA interactions from GRanges object.

### Usage

```
rna2rnaR(chimGR, geneGR, enhGR)
```

### Arguments

chimGR	Chimeric junction GRanges object. It should be made from ChimPRO output.
geneGR	Gene annotation GRanges object. It should be made from annGE\$gene.
enhGR	Enhancer annotation GRanges object. It should be made from annGE\$erna.

### Value

bedpe type table. xx.x and xx.y are the target pairs

---

stringS	<i>Process Gene String</i>
---------	----------------------------

---

### Description

Splits a comma-separated gene string into a character vector and trims any surrounding white spaces.

### Usage

```
stringS(ss)
```

### Arguments

ss	A single character string with gene names separated by commas (e.g. "gene1, gene2 , gene3").
----	--

### Value

A character vector of cleaned gene names.

---

`subDB`*Filter a list of data frames by column and value*

---

**Description**

This function filters each data frame in a list by a specific value in a specified column. It skips any data frames that do not contain the column.

**Usage**

```
subDB(db, col, value)
```

**Arguments**

<code>db</code>	A list of data frames.
<code>col</code>	The name of the column to filter by (e.g., "E" or "G").
<code>value</code>	The value to filter for.

**Value**

A subset of the db

**Examples**

```
subDB(emi, "E", "en100035")
```

---

`wide2long`*Pivot a wide db table to long*

---

**Description**

Converts wide emi db table to long format for processing

**Usage**

```
wide2long(df, keep_cols)
```

**Arguments**

<code>df</code>	A data frame in wide format.
<code>keep_cols</code>	A character vector of column names to retain (not pivot).

**Value**

A data frame in long format with columns: the retained identifiers, a 'variable' column for the former column names, and a 'value' column for the values.

---

winLoc	<i>Generate location-based subsets from emi loc table</i>
--------	---

---

**Description**

This function processes the emi db loc table.

**Usage**

```
winLoc(subloc)
```

**Arguments**

subloc                      emi\$loc subset preferred.

**Details**

It returns: - p1: CPM values split by RNA type (only cytosol and nucleus) - p2: REI values for 'cytosol' polyA+ RNA split by Cell line - p3: REI values comparing subcellular cytoplasmic compartments to cytosol (total RNA), split by Enhancer (E) - d: The original filtered input dataframe

**Value**

A named list with components: 'p1', 'p2', 'p3', and 'd'.
